

| Serious Asthma Events with Fluticasone plus Salmeterol versus Fluticasone Alone Stempel DA et al. N Engl J Med 2016; 374:1822-1830 | |
|--|---|
| Background | The safety of using a LABA together with an ICS in asthma therapy is questioned after results of the Serevent Nationwide Surveillance (SNS), Salmeterol Multicenter Asthma Research Trial (SMART), and a meta-analysis conducted by the FDA in 2010 associated LABA use with asthma-related hospitalizations, intubations, and death. |
| Rationale | Stempel et al. conducted their study in response to the FDA's 2010 request for each manufacturer of a LABA to prospectively evaluate whether the ICS/LABA combination is non-inferior to ICS use alone with respect to the occurrence of serious asthma-related events. Serious asthma-related events are defined as hospitalization, endotracheal intubation, or death. |
| Objective | <ul style="list-style-type: none"> • Primary (Safety): To assess whether the use of a fixed dose combination of fluticasone/salmeterol is non-inferior to the use of fluticasone alone with respect to the risk of asthma-related adverse events (hospitalization, intubation, and death). • Secondary (Efficacy): To assess whether the use of fluticasone/salmeterol is superior to the use of fluticasone alone in asthma therapy as indicated by the incidence of asthma exacerbations and frequency of albuterol/salbutamol use. |
| Trial Design | <ul style="list-style-type: none"> • Global (33 countries), multicenter (710 centers), prospective, randomized, stratified, double-blind, non-inferiority trial. • Randomization: interactive voice-response system and stratified into 6 groups based on ACQ-6 score (either < 1.5 or ≥ 1.5) and current asthma medications, then assigned to one of the two interventions on a 1:1 basis according to their stratification group. • Recruitment period: November 2011 to June 2015. • Both interventions were identically packaged; however, the dose of ICS was not double-blinded. All subjects had access to open-label rescue SABA therapy (albuterol, salbutamol MDI). • Total of a 26 week treatment period, which was followed by a 1 week follow-up period. |
| Patient Population | Men and women ≥ 12 years old with moderate-to-severe asthma present for at least 1 year prior to study enrollment. |
| Eligibility | <p>Inclusion Criteria:</p> <ul style="list-style-type: none"> • Informed consent • Males and females ≥ 12 years old • Persistent asthma for at least 1 year prior to study recruitment • Require daily asthma therapy • Asthma exacerbation within past year treated with glucocorticoids or hospitalization <p>Exclusion Criteria:</p> <ul style="list-style-type: none"> • Asthma exacerbation treated with glucocorticoids or hospitalization that occurred 30 days prior to randomization • Life-threatening asthma • > 10 pack-years smoker • Unstable asthma • Pregnant or breastfeeding |
| Intervention | <ol style="list-style-type: none"> 1. Fluticasone/salmeterol: 100/50 mcg, 250/50 mcg, or 500/50 mcg given BID 2. Fluticasone: 100 mcg, 250 mcg, or 500 mcg given BID |
| Outcomes | <p>Primary Endpoint:</p> <ul style="list-style-type: none"> • <i>Safety:</i> First serious asthma-related event (hospitalization, endotracheal intubation, or death) <p>Secondary Endpoints:</p> <ul style="list-style-type: none"> • <i>Efficacy:</i> First severe asthma exacerbation requiring glucocorticoid therapy for a minimum x 3/7 with or without hospitalization or ED visit. • <i>Efficacy:</i> Albuterol or salbutamol use as rescue therapy. |
| Statistics | <p>Primary Safety Endpoint:</p> <ul style="list-style-type: none"> • Stratified Cox proportional-hazards regression model • Intention-to-treat analysis of all patients who received at least one dose of their randomly assigned intervention. • Based on the findings of a 2008 meta-analysis conducted by GSK for the FDA Advisory Committee, it was assumed that the rate of serious asthma-related events in the fluticasone only group would be 0.0075 over the 26 week treatment period. • An upper boundary of < 2.0 on the 95% CI was defined to mean that the fluticasone-salmeterol intervention was non-inferior to fluticasone alone in terms of the primary composite safety endpoint. • A sample size of 11, 664 gives the study a power of 90% to detect non-inferiority of fluticasone/salmeterol compared to |

| | <p>fluticasone alone using a one-sided α of 0.025.</p> <p><u>Secondary Efficacy Endpoints:</u></p> <ul style="list-style-type: none"> • Cox proportional-hazards regression model • The study was not powered for statistical analysis of the secondary endpoints, so descriptive analysis of the data obtained was reported. | | | | | | | | | | | | | | | | | | | | | |

| Bottom Line (Conclusion) | <p>In patients with moderate-to-severe asthma the use of a fixed dose combination of fluticasone/salmeterol over a 26 week period was non-inferior to use of fluticasone alone in terms of occurrence of severe asthma-related events (death, endotracheal intubation, or hospitalization). These adverse events occurred at a similar frequency in both interventions.</p> <p>The fixed dose combination of fluticasone/salmeterol showed to have a lower risk of asthma exacerbation (21%) compared to fluticasone use alone; however, the study was not powered for this secondary efficacy endpoint.</p> | | | | | | | | | | | | | | | | | | | | | |
| Limitations | <ul style="list-style-type: none"> • Short duration (26 weeks) • Infrequent incidence of serious asthma-related events • Studied moderate-to-severe asthmatics (cannot extrapolate to patients with life-threatening or unstable asthma) • High adherence rates seen in study may not be applicable to real world setting (median rate of adherence was 95.1% in both interventions) • Underlying inflammation severity was not assessed | | | | | | | | | | | | | | | | | | | | | |
| Application to Clinical Practice | <ul style="list-style-type: none"> • Trial findings help confirm that in patients who are highly adherent to their asthma therapy and do not have either life-threatening or unstable asthma the use of the LABA/ICS combination does not increase the risk of serious asthma related events compared to ICS use alone. • The results cannot be applied to patients who have severe unstable disease, which are patients for whom it is recommended to initiate therapy with a LABA/ICS combination. | | | | | | | | | | | | | | | | | | | | | |
